Abstract

The Javalambre Photometric Local Universe Survey (J-PLUS; Cenarro et al. 2018), is observing thousands of square degrees of the northern sky from the Observatorio Astrofísico de Javalambre (OAJ) in Teruel, Spain. The survey is being carried out with the 0.83 meter JAST/T80 telescope and the panoramic camera T80Cam with a 2 deg^2 FoV. A set of twelve broad, intermediate, and narrow band optical filters is used. The large FoV, the position of the filters, and the survey strategy; are suitable to perform science that will expand our knowledge in many fields of astrophysics. More concretely, the $J0660$ narrow-band filter covers the $\text{H}\alpha$ emission-line flux of nearby galaxies up to $z \leq 0.017$, making J-PLUS a powerful tool to study the 2D star formation rate (SFR) properties of these galaxies.
